Amendments to the Specification:

In response to the Examiner's objection to the specification, please replace the paragraph at Page 6, line 26 as follows:

["]The HTTP Post method is more challenging than is a GET request because the accompanying arguments may be sent in any desired MIME (Multipurpose Internet Mail Extensions) format. POST operations are typically used to submit information on a completed HTML form to an application server. In such cases, variables in the form are typically identified in the header as Content-Type: application/x-www-form-urlencoded as shown below in a POST example. The user could choose an option on the form that would specify the user's contact point as the directory number of whichever portal is currently being used to connect to the network.
